Q:20

$$(1+x^2)\frac{dy}{dx} = e^{m\tan^{-1}x} - y$$

$$(1+x^2)\frac{dy}{dx} + y = e^{m\tan^{-1}x}$$

$$\frac{dy}{dx} + \frac{y}{1+x^2} = \frac{e^{m\tan^{-1}x}}{1+x^2}$$

comparing it with

$$\frac{dy}{dx} + Py = Q \rightarrow \text{linear differential equation}$$

$$P = \frac{1}{1+x^2}$$

$$I.F = e^{\int P\,dx}$$

$$= e^{\int \frac{1}{1+x^2}dx}$$

$$\left\{ \int \frac{1}{x^2+1}dx = \tan^{-1}x \right\}$$

$$I.F = e^{\tan^{-1}x}$$

So ~~dif~~ equation becomes

$$y \; I.F = \int Q \times I.F \, dx + c$$

$$y \times e^{\tan^{-1}x} = \int \frac{e^{m\tan^{-1}x}}{1+x^2} \times e^{\tan^{-1}x} dx + c$$

$$y \times e^{\tan^{-1}x} = \int \frac{e^{(m+1)\tan^{-1}x}}{1+x^2} dx + c$$

put $\tan^{-1}x = t$

$$\frac{1}{1+x^2} dx = dt$$

$$y e^{\tan^{-1}x} = \int e^{(m+1)t} \times dt + c$$

$$y e^{\tan^{-1}x} = \frac{e^{(m+1)t}}{(m+1)} + c$$

~~y to~~ $y e^{\tan^{-1}x} = \dfrac{e^{(m+1)\tan^{-1}x}}{m+1} + c$

when $x = 0 \quad y = 1$

$$ye^{\tan^{-1}x} = \frac{e^{(m+1)\tan^{-1}x}}{(m+1)} + c$$

when $x=0$ $y=1$

$$1 \times e^{\tan^{-1}0} = \frac{e^{(m+1)\tan^{-1}0}}{(m+1)} + c$$

$$1 \times e^{0} = \frac{e^{(m+1)(0)}}{m+1} + c \qquad e^0 = 1$$

$$1 = \frac{1}{m+1} + c$$

$$1 - \frac{1}{m+1} = c$$

$$\frac{m + \cancel{1} - \cancel{1}}{m+1} = c$$

$$c = \frac{m}{m+1}$$

So equation is

$$\left[ye^{\tan^{-1}x} = \frac{e^{(m+1)\tan^{-1}x}}{(1+m)} + \frac{m}{m+1} \right]$$

Q: 21.

$f(x) = \sin^2 x - \cos x \quad x \in [0, \pi]$

$f'(x) = 2\sin x \cos x - (-\sin x)$

$f'(x) = 2\sin x \cos x + \sin x$

put $f'(x) = 0$

then $(2\sin x \cos x + \sin x) = 0$

$\sin x (2\cos x + 1) = 0$

$\sin x = 0$ or $\cos x = -\frac{1}{2}$

$x = 0, \pi$ or $x = \frac{2\pi}{3}$

both the extreme value are automatically included.

so $f(0) = [\sin(0)]^2 - \cos 0$

$= 0 - 1$

$= -1$

$f(\pi) = \sin^2\pi - \cos\pi$

$= 0 - (-1)$

$= 1$

$f\left(\frac{2\pi}{3}\right) = \sin^2\frac{2\pi}{3} - \cos\frac{2\pi}{3}$

$= \left(\frac{\sqrt{3}}{2}\right)^2 - \left(-\frac{1}{2}\right) = \frac{3}{4} + \frac{1}{2} = \frac{10}{8} = \frac{5}{4}$

$f(0) = -1$

$f(\pi) = 1$

$f(\frac{2\pi}{3}) = \frac{5}{4}$

So $\boxed{\text{Absolute maxima is } \frac{5}{4} \text{ at } x = \frac{2\pi}{3}}$

$\boxed{\text{Absolute minima is } -1 \text{ at } x = 0}$

Q : 22 :

$\vec{r} = \hat{i} + \hat{j} + \hat{k} + \lambda(\hat{i} - \hat{j} + \hat{k})$

$\vec{r} = 4\hat{j} + 2\hat{k} + \mu(2\hat{i} - \hat{j} + 3\hat{k})$

These line are coplaner if they are parallel or they are intersecting

But these lines are not parallel.

So they are coplaner if shortest distance between them is zero:

$a_1 = (1, 1, 1)$ $\quad$ $(a_2 - a_1) = (-1, 3, 1)$

$a_2 = (0, 4, 2)$

$b_1 = \langle 1, -1, 1 \rangle$

$b_2 = \langle 2, -1, 3 \rangle$

Shortest distance $= \dfrac{|(\vec{a_2} - \vec{a_1}) \cdot (\vec{b_1} \times \vec{b_2})|}{|\vec{b_1} \times \vec{b_2}|}$

Let us find $|(\vec{a_2} - \vec{a_1}) \cdot (\vec{b_1} \times \vec{b_2})|$

$$(\vec{a_2} - \vec{a_1}) \cdot (\vec{b_1} \times \vec{b_2}) = \begin{vmatrix} -1 & 3 & 1 \\ 1 & -1 & 1 \\ 2 & -1 & 3 \end{vmatrix}$$

(expanding by 1st row)

$$= -1(-3+1) - 3(3-2) + 1(-1+2)$$
$$= -1(-2) - 3(1) + 1$$
$$= 2 + 1 - 3$$
$$= 0$$

So shortest distance between the lines is zero

So they are coplaner.

Let $\langle a, b, c \rangle$ be the direction ratio of normal to the plane.
So the dot product of direction ratio of normal to plane and the direction ratio of line is 0.

So $\quad a - b + c = 0$

$\quad\quad 2a - b + 3c = 0$

$$\frac{a}{\quad} \quad \frac{b}{\quad} \quad \frac{c}{\quad}$$

$$\begin{array}{cccc} -1 & 1 & 1 & -1 \\ -1 & 3 & 2 & -1 \end{array}$$

$$\frac{a}{-3+1} = \frac{b}{2-3} = \frac{c}{-1+2}$$

So $\langle a, b, c \rangle = \langle -2, -1, 1 \rangle$

So passing point of line is also the passing point of plane

So passing point $= (1, 1, 1)$

So equation becomes

$$-2(x-1)-1(y-1)+1(z-1)=0$$

$$-2x+2-y+\cancel{1}+z-\cancel{1}=0$$

$$\boxed{-2x-y+z+2=0}$$

$\downarrow$

equation of plane.

Q:23 $f: W \to W$

$$f(n) = \begin{cases} n-1 & \text{if } n \text{ is odd} \\ n+1 & \text{if } n \text{ is even} \end{cases}$$

To prove that it is one-one:

Let us suppose that $n_1, n_2 \in W$

$n_1 \neq n_2$ but $f(n_1) = f(n_2)$

(i) 1st case: if n_1 & n_2 are odd

$$f(n_1) = f(n_2)$$

$$n_1 - \cancel{1} = n_2 - \cancel{1}$$

$n_1 = n_2$ which is contradiction.

(ii) 2nd case : x_1, x_2 are even

$f(x_1) = f(x_2)$

$x_1 + \cancel{1} = x_2 + \cancel{1}$

$x_1 = x_2$

which is contradiction.

(iii) 3rd case if x_1 is even & x_2 is odd

$f(x_1) = f(x_2)$

$x_1 + 1 = x_2 - 1$

$x_1 + 2 = x_2$

$\downarrow$ even $\quad \downarrow$ odd

if we add 2 in an even no. then we get an even no. but x_2 is odd which is again contradiction

So from these 3 point we see that

$f(x_1) = f(x_2)$ only if $x_1 = x_2$

$\Rightarrow$ f is one-one.

To prove that f is onto:

Let $y \in W$
and y is even
then $y+1$ is odd and it belongs in whole no.
~~$f(x_1$~~ $f(y+1) = y+1-1$
$= y$

So for every $y \in W$ which is even there exist a preimage $y+1$ which is odd and $(y+1) \in W$

Let $y \in W$
y is odd
then $y-1$ is even and $y-1 \in W$
$f(y-1) = y-1+1$
$= y$

So for every $y \in W$ which is odd there exist a pre image $y-1 \in W$ which is even.
So for all $y \in W$ there exist pre image in whole no.
So f is onto.

f is one-one and onto So it is invertible

To find $f^{-1}(x)$

$y = x - 1$ if x is odd

y here is even

$y + 1 = x$

So $x = y + 1$ if y is even

$f^{-1}(x) = x + 1$ if x is even

$y = x + 1$ if x is even

y is odd here

$y - 1 = x$

So $f^{-1}(x) = x - 1$ if x is odd

So $f^{-1}(x) = \begin{cases} x-1 & \text{if } x \text{ is odd} \\ x+1 & \text{if } x \text{ is even} \end{cases}$

$\boxed{x \in W}$ So $\boxed{f^{-1} = f}$

$y = x-1$ if $x \geq 1$

$y = -x+1$ if $x < 1$

intersection point :

$y = \sqrt{5-x^2}$

$y = x-1$

So $\sqrt{5-x^2} = (x-1)$

$5-x^2 = x^2+1-2x$

$2x^2-2x-4=0$

$\cancel{2}x^2-x-2=0$

$x^2-2x+x-2=0$

$x(x-2)+1(x-2)=0$

So $x=2$ or $x=-1$

$x=2$ rejected as $x \geq 1$

$y = \sqrt{5 - x^2}$

$y = -x + 1$

$y \quad x < 1$

$5 - x^2 = x^2 + 1 - 2x$

So $x = 2, -1$

$x = 2$ $\downarrow$ rejected $\quad \boxed{x = -1}$

$R_1 \to R_1 + R_2 + R_3$

$$\Delta = \begin{vmatrix} 3x+7 & 3x+7 & 3x+7 \\ x+6 & x-1 & x+2 \\ x-1 & x+2 & x+6 \end{vmatrix}$$

$$\Delta = 3x+7 \begin{vmatrix} 1 & 1 & 1 \\ x+6 & x-1 & x+2 \\ x-1 & x+2 & x+6 \end{vmatrix}$$

$$\Delta = (3x+7) \begin{vmatrix} 0 & 0 & 1 \\ 7 & -3 & x+2 \\ -3 & -4 & x+6 \end{vmatrix}$$

expanding by R_1

$\Delta = (3x+7)\,[-28 - 9]$

$\Delta = 0$

$\Rightarrow 3x+7=0$

$\boxed{x = \frac{-7}{3}}$

$$A = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 1 \end{bmatrix}$$

$$A^2 = AA = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 1 \end{bmatrix} \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 1 \end{bmatrix}$$

$$A^2 = \begin{bmatrix} 1+4+4 & 2+2+4 & 2+4+2 \\ 2+2+4 & 4+1+4 & 4+2+2 \\ 2+4+2 & 4+2+2 & 4+4+1 \end{bmatrix}$$

$$A^2 = \begin{bmatrix} 9 & 8 & 8 \\ 8 & 9 & 8 \\ 8 & 8 & 9 \end{bmatrix}$$

$$A^2 - 4A - 5I = \begin{bmatrix} 9 & 8 & 8 \\ 8 & 9 & 9 \\ 8 & 8 & 9 \end{bmatrix} + \begin{bmatrix} -4 & -8 & -8 \\ -8 & -4 & -8 \\ -8 & -8 & -4 \end{bmatrix} + \begin{bmatrix} -5 & 0 & 0 \\ 0 & -5 & 0 \\ 0 & 0 & -5 \end{bmatrix}$$

$$A^2 - 4A - 5I = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = O$$

So $A^2 - 4A - 5I = O$

Hence proved.

$A^2 - 4A - 5I = 0$

pre-multiplying by A^{-1}

$A^{-1}AA - 4A^{-1}A - 5A^{-1}I = 0$

$A^{-1}A = I$

$IA - 4I - 5A^{-1} = 0$

$IA = A$

$A - 4I - 5A^{-1} = 0$

$A - 4I = 5A^{-1}$

$$A^{-1} = \frac{A - 4I}{5}$$

$$A^{-1} = \frac{1}{5}\left[A - 4I\right]$$

$$5A^{-1} = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 1 \end{bmatrix} + \begin{bmatrix} -4 & 0 & 0 \\ 0 & -4 & 0 \\ 0 & 0 & -4 \end{bmatrix}$$

$$5A^{-1} = \begin{bmatrix} -3 & 2 & 2 \\ 2 & -3 & 2 \\ 2 & 2 & -3 \end{bmatrix}$$

So $A^{-1} = \frac{1}{5}\begin{bmatrix} -3 & 2 & 2 \\ 2 & -3 & 2 \\ 2 & 2 & -3 \end{bmatrix}$

11.

$$\sin^{-1}(1-x) - 2\sin^{-1}x = \frac{\pi}{2}$$

$$\sin^{-1}(1-x) = \frac{\pi}{2} + 2\sin^{-1}x$$

$$(1-x) = \sin\left(\frac{\pi}{2} + 2\sin^{-1}x\right)$$

$$(1-x) = \cos(2\sin^{-1}x)$$

$$\sin^{-1}x = \theta$$
$$x = \sin\theta$$

$$\cos 2\theta = 1 - 2\sin^2\theta$$
$$\cos 2\theta = 1 - 2x^2$$

$$\Rightarrow \quad 1 - x = \cos 2\theta$$
$$1 - x = 1 - 2x^2$$

$$\Rightarrow \quad 2x^2 - x = 0$$
$$x(2x - 1) = 0$$

$x = 0$ or $x = \frac{1}{2}$

put $x = \frac{1}{2}$ in equation

$\sin^{-1}\frac{1}{2} - 2\sin^{-1}\frac{1}{2}$

$= \frac{\pi}{6} - 2 \times \frac{\pi}{6}$

$\neq \frac{\pi}{2}$

So $x \neq \frac{1}{2}$

So $\boxed{x = 0}$

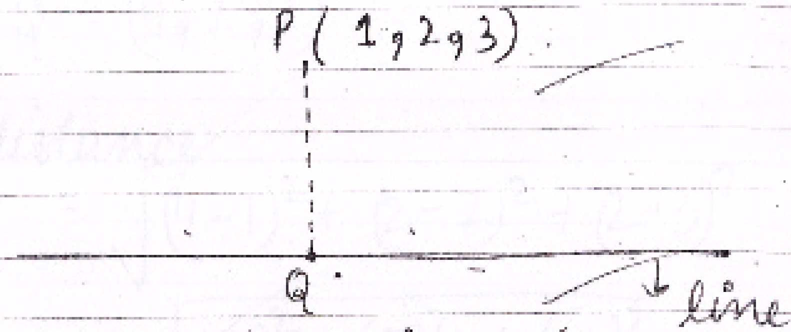
passing point of line $= (4, 2, 2)$
since $\vec{b}$ is $\parallel$ to line
So direction ratio of line $= \langle 2, 3, 6 \rangle$

So equation of line

$$\frac{x-4}{2} = \frac{y-2}{3} = \frac{z-2}{6} = \lambda$$

general point on line

$(2\lambda+4, 3\lambda+2, 6\lambda+2)$



Q be the foot of ⊥ar

PQ is ⊥ar to line

So dot product of direction ratio of line and PQ is 0

direction ratio of PQ $= \langle 2\lambda+3, 3\lambda, 6\lambda-1 \rangle$

So according to question:

$2.(2\lambda+3) + (3\lambda)3 + 6(6\lambda-1) = 0$

$4\lambda + \cancel{6} + 9\lambda + 36\lambda - \cancel{6} = 0$

$\boxed{\lambda = 0}$

So point $Q = (4, 2, 2)$

So ⊥ar distance

$PQ = \sqrt{(4-1)^2 + (2-2)^2 + (2-3)^2}$

$= \sqrt{(3)^2 + (0)^2 + (-1)^2}$

$= \sqrt{9+1}$

$\boxed{\text{length of ⊥ar} = \sqrt{10} \text{ unit}}$

~~AB~~

these A, B, C, D are coplaner

~~So~~ $\overrightarrow{AB}\cdot(\overrightarrow{BC}\times\overrightarrow{CD}) = 0$

triple product is 0.

$\overrightarrow{AB} = 1\hat{i} + (x-1)\hat{j} + 4\hat{k}$

$\overrightarrow{BC} = 0\hat{i} + (1-x)\hat{j} - 7\hat{k}$

$\overrightarrow{CD} = 2\hat{i} + 3\hat{j} + \hat{k}$

$$\overrightarrow{AB}\cdot(\overrightarrow{BC}\times\overrightarrow{CD}) = \begin{vmatrix} 1 & x-1 & 4 \\ 0 & 1-x & -7 \\ 2 & 3 & 1 \end{vmatrix} = 0$$

expanding by R_1

$1(1-x+21) - (x-1)14 + 4(2(x-1)) = 0$

$22 - x - 14x + 14 + 8x - 8 = 0$ $\quad \boxed{x = 4}$

$-7x = -28$

p (probability of success) $= \frac{1}{2}$
i.e that head comes

q (probability of failure) $= \frac{1}{2}$
i.e that tail comes

Let the coin be tossed n times

this event follow the conditions of bernoulli trial

X be the random variable = no of heads

$P(X \geq 1) = P(1) + \cdots + P(n)$

$P(X \geq 1) = 1 - P(0)$

$= 1 - {}^{n}C_0 \times \left(\frac{1}{2}\right)^0 \left(\frac{1}{2}\right)^n$

P(X ≥ 1) should be more than 80%.

$P(X \geq 1) > \frac{8}{10}$

$\frac{80}{100} < 1 - \left(\frac{1}{2}\right)^n$

$$1-\left(\frac{1}{2}\right)^n \geq \frac{8}{10}$$

$$\left(1-\frac{8}{10}\right) \geq \left(\frac{1}{2}\right)^n$$

$$\frac{1\cancel{2}}{5\cancel{10}} > \left(\frac{1}{2}\right)^n$$

$$5 < 2^n$$

$$n = 3$$

follow the condition

So the coin should be tossed at least 3 times.

put $x^2 = t$

then $\frac{t}{(t-1)(t+2)} = \frac{A}{t-1} + \frac{B}{t+2}$

$t = A(t+2) + B(t-1)$

put $t = 1$

$1 = A \times 3$
